A large, brown elephant stands behind a small, bright orange ball on a light-colored surface. The elephant's head is turned slightly to the right, and its trunk is visible. The background is blurred, showing more of the elephant and some vertical structures.

Bayes and Topic Models

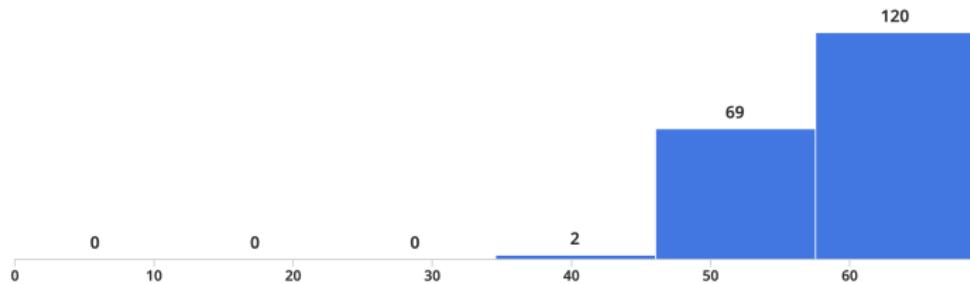

October 26

Yale

Quick notes

- Assignment 3 due tonight
- Two more to go!
- Midterm scores and mid-semester totals posted (will be adjusted to account for percentages—stay tuned)
- Announcement later today about mid-semester letter grades
- Quiz 4 next week

Midterm

Minimum	Median	Maximum	Mean	Std Dev <small>?</small>
36.0	60.0	69.0	58.82	5.65

Reminder

- If you need to email me about any issues with your work for the course, copy the course manager Joanne Chen (haoting.chen@yale.edu)
- Otherwise, your email may not be answered

For Today

- Mixtures
- Introduction to Bayesian analysis
- Overview of topic models

Where are we going?

- So far: Mostly “surface representations” & explicit features
 - ▶ Listing information for CA housing
 - ▶ Supernovæ classification — measured light

Where are we going?

- So far: Mostly “surface representations” & explicit features
 - ▶ Listing information for CA housing
 - ▶ Supernovæ classification — measured light
- Next: “Hidden” representations and latent variables

George Washington

1789

Among the many interesting objects which will engage your attention that of providing for the common defense will merit particular regard. To be prepared for war is one of the most effectual means of preserving peace.

Franklin Roosevelt

1941

Such a peace would bring no security for us or for our neighbors. As a nation, we may take pride in the fact that we are softhearted; but we cannot afford to be soft-headed.

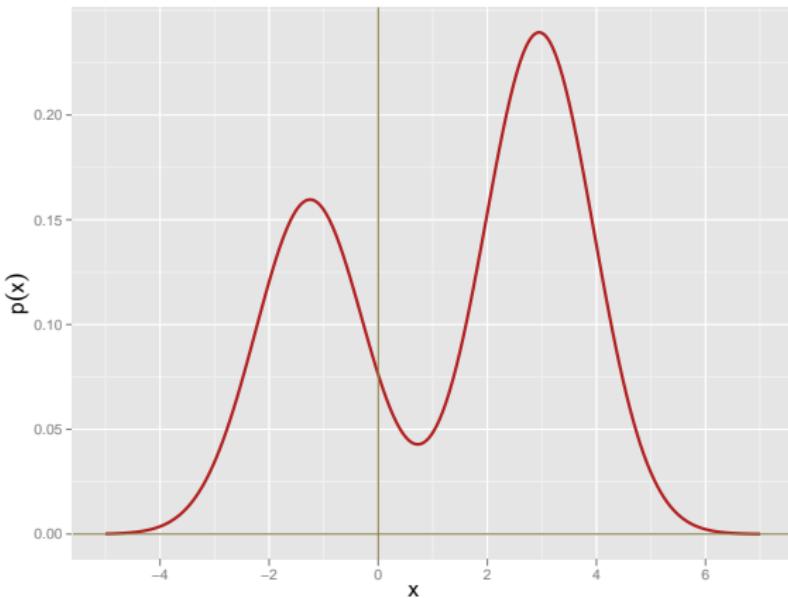

The elephants in the room

Mixtures

- Key technique: Mixture models
- Mixtures have latent variables
- Flexible tool
- Simple and difficult at the same time

Gaussian Mixture

Mixture of two normals, one with mean $-\frac{5}{2}$, another with mean 3.

Mixtures

- For each data point, we have a hidden (latent) variable: Which Gaussian generated the data point?
- $Z = 1$ it was generated from one model; $Z = 0$ it was generated from the other model
- We don't *observe* Z , it could be either value

Mixtures

- *Mixture of f and g:*

$$p(x) = \theta f(x) + (1 - \theta)g(x)$$

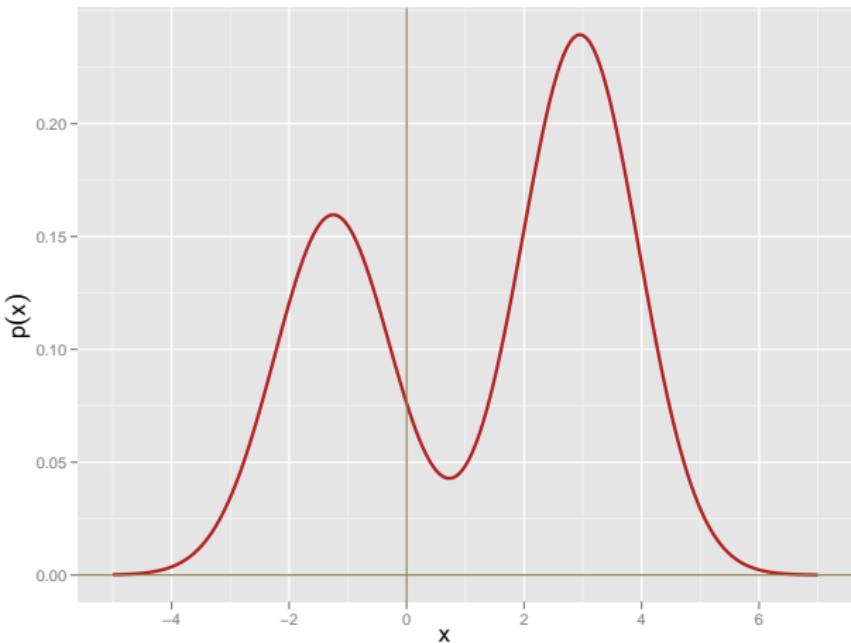

Simplest, most common kind of latent variable model

- *Hidden variable representation:* Define $Z \sim \text{Bernoulli}(\theta)$ and

$$p(x) = \sum_{z=0,1} p(x | z) p(z)$$

with $p(x | 1) = f(x)$, $p(x | 0) = g(x)$, $p(z) = \theta^z(1 - \theta)^{(1-z)}$.

Gaussian Mixture: All the Key Concepts

Bayesian Inference

The parameter θ of a model is viewed as a random variable.
Inference usually carried out as follows:

- Choose a *generative model* $p(x | \theta)$ for the data.
- Choose a *prior distribution* $\pi(\theta)$ that expresses beliefs about the parameter before seeing any data.
- After observing data $\mathcal{D}_n = \{x_1, \dots, x_n\}$, update beliefs and calculate the *posterior distribution* $p(\theta | \mathcal{D}_n)$.

Bayes' Theorem

A simple consequence of conditional probability:

$$\begin{aligned}\mathbb{P}(A | B) &= \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} \\ &= \frac{\mathbb{P}(B | A) \mathbb{P}(A)}{\mathbb{P}(B)}\end{aligned}$$

Bayes' Theorem

The posterior distribution can be written as

$$p(\theta | x_1, \dots, x_n) = \frac{p(x_1, \dots, x_n | \theta) \pi(\theta)}{p(x_1, \dots, x_n)} = \frac{\mathcal{L}_n(\theta) \pi(\theta)}{c_n} \propto \mathcal{L}_n(\theta) \pi(\theta)$$

where $\mathcal{L}_n(\theta)$ is the *likelihood function* and

$$c_n = p(x_1, \dots, x_n) = \int \mathcal{L}_n(\theta) \pi(\theta) d\theta$$

is the normalizing constant, which is also called *evidence*.

Important Example

Take model $X \sim \text{Bernoulli}(\theta)$.

This is a “coin flip”: $X = 1$ means “heads” and $X = 0$ means “tails.”

Natural prior is $\text{Beta}(\alpha, \beta)$ distribution

$$\pi_{\alpha, \beta}(\theta) \propto \theta^{\alpha-1} (1-\theta)^{\beta-1}$$

Important Example

Take model $X \sim \text{Bernoulli}(\theta)$.

Natural prior is $\text{Beta}(\alpha, \beta)$ distribution

$$\pi_{\alpha, \beta}(\theta) \propto \theta^{\alpha-1} (1-\theta)^{\beta-1}$$

The scaling constant is scary looking:

$$\frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)}$$

where $\Gamma(\cdot)$ is the “Gamma function”

$$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx$$

Important Example

$X \sim \text{Bernoulli}(\theta)$ with data $\mathcal{D}_n = \{x_1, \dots, x_n\}$. Prior Beta(α, β) distribution

$$\pi_{\alpha, \beta}(\theta) \propto \theta^{\alpha-1} (1-\theta)^{\beta-1}$$

Let $s = \sum_{i=1}^n x_i$ be the number of “heads”

Posterior distribution $\theta | \mathcal{D}_n$ is another beta distribution!

Specifically, with

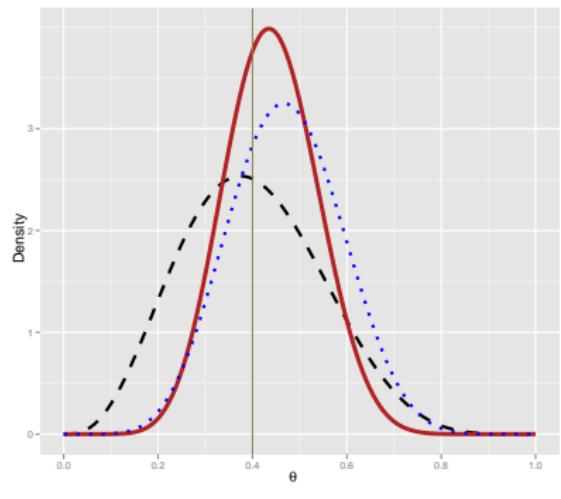

$$\tilde{\alpha} = \alpha + \text{number of heads} = \alpha + s$$

$$\tilde{\beta} = \beta + \text{number of tails} = \beta + n - s$$

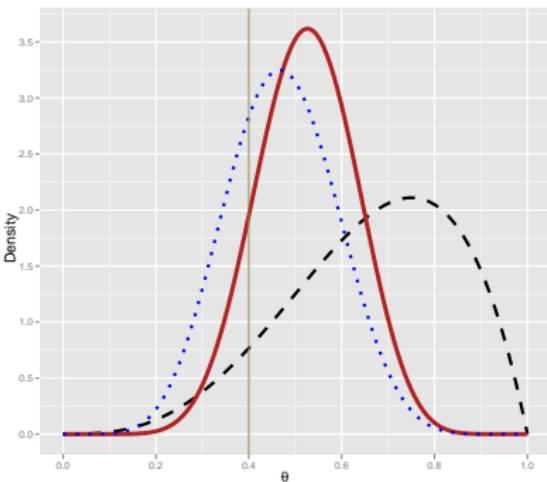

Showing this just uses the simple fact that $\theta^{\alpha-1} \theta^x = \theta^{x+\alpha-1}$

Example

$n = 15$ points sampled as $X \sim \text{Bernoulli}(\theta = 0.4)$, with $s = 7$ heads.

prior A

prior B

Prior distribution (black-dashed), likelihood function (blue-dotted), posterior distribution (red-solid).

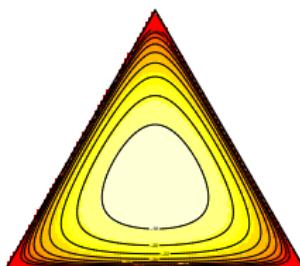

Dirichlet

Multinomial model with Dirichlet prior is generalization of the Bernoulli/Beta model.

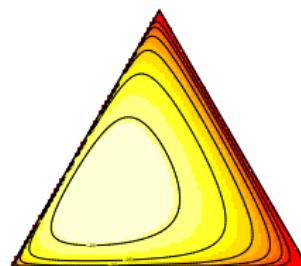

$$\text{Dirichlet}_{\alpha}(\theta) \propto \theta_1^{\alpha_1-1} \theta_2^{\alpha_2-1} \cdots \theta_K^{\alpha_K-1}$$

where $\alpha = (\alpha_1, \dots, \alpha_K) \in \mathbb{R}_+^K$ is a non-negative vector.

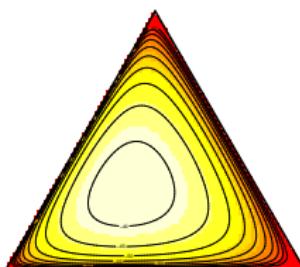

Example

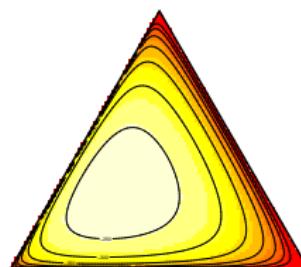

prior with Dirichlet(6,6,6)

likelihood function with $n = 20$

posterior distribution with $n = 20$

posterior distribution with $n = 200$

How The Economist presidential forecast works

THIS YEAR, *The Economist* is publishing its first-ever statistical forecast of an American presidential election. Developed with the assistance of Andrew Gelman and Merlin Heidemanns, political scientists at Columbia University, our model calculates Joe Biden's and Donald Trump's probabilities of winning each individual state and the election overall. Its projections will be updated every day at <https://projects.economist.com/us-2020-forecast/president>.

In another first, we are [publishing the source code](#) for what we believe to be the most innovative section of the model. All readers are welcome to download it, explore how it works, tweak its parameters and run it

Example: Election Forecasting

<https://projects.economist.com/us-2020-forecast/president/how-this-works>

Back to Bayes-ics

Readers acquainted with the workings of similar forecasting models may be surprised that the phrase “state polls” has not yet entered the equation. This exclusion is by design. Our model follows a logical structure first developed by Thomas Bayes, an 18th-century reverend whose ideas have shaped a large and growing family of statistical techniques. His approach works in two stages. First, before conducting a study, researchers

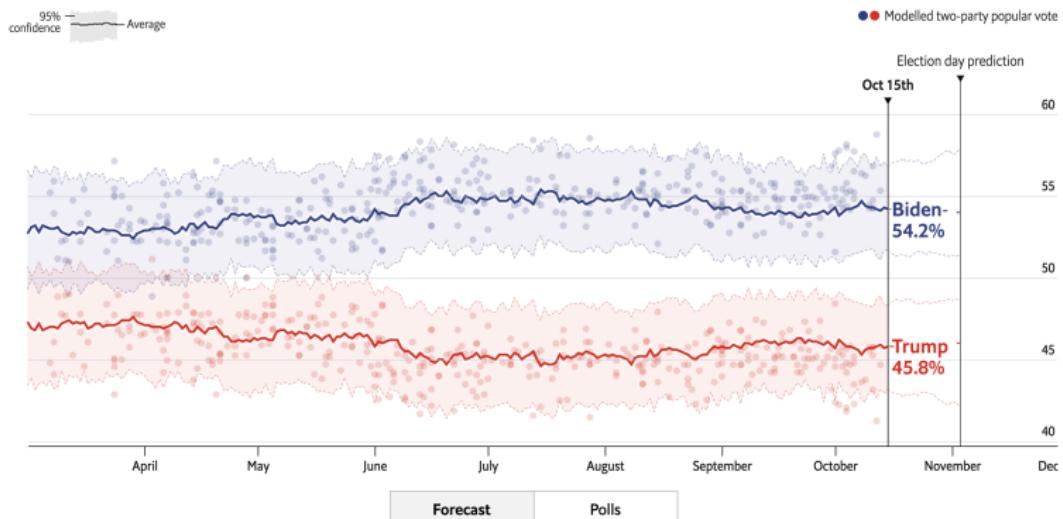

explicitly state what they believe to be true, and how confident they are in that belief. This is called a “prior”. Next, after acquiring data, they update this prior to reflect the new information—gaining more confidence if it confirms the prior, and generally becoming more uncertain if it refutes the prior (though not if the new numbers are so definitive that leave little room for doubt). In this framework, the expected distribution of potential vote shares in each state derived above is the prior, and state polls that trickle in during the course of the campaign are the new data. The result—a “posterior”, in Bayesian lingo—is our forecast.

Example: Election Forecasting

<https://projects.economist.com/us-2020-forecast/president/how-this-works>

Modelled popular vote on each day

The model first averages the polls, weighting them by their sample sizes and correcting them for tendencies to overestimate support for one party. It then combines this average with our forecast based on non-polling data, pulling vote shares on each day slightly towards the final election-day projection.

Let's go to the notebook!

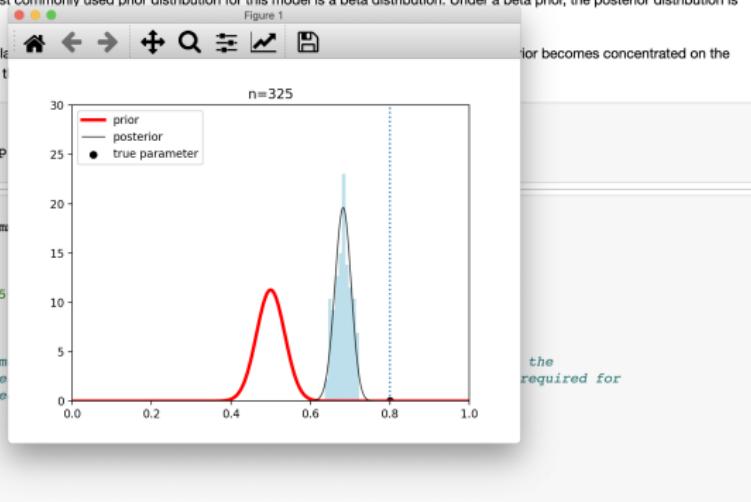

Demo code for Bayesian analysis

In this notebook we illustrate some of the basic models and priors for Bayesian Inference. These concepts will be important for our discussions about "topic models."

First, we illustrate the situation where the parameter θ that we are modeling is a Bernoulli parameter. This can be thought of as the probability that flipping a certain coin comes up heads. The most commonly used prior distribution for this model is a beta distribution. Under a beta prior, the posterior distribution is again a beta distribution.

This is illustrated in the following simulation. As the sample size increases, the posterior distribution becomes concentrated on the true parameter. But as the variance of the

```

import numpy as np  
import matplotlib.pyplot as plt  
  
In [*]: %matplotlib qt  
from scipy.special import gammainc  
from scipy import random  
from scipy.stats import beta  
  
theta = np.linspace(0,1,num=5  
fig = plt.figure(1)  
plt.ion()  
  
# The following are the parameters of the prior  
# variance of the prior decreases as the sample size increases  
# the posterior to be centered around the true parameter  
  
scale = 100  
a0 = scale*1  
b0 = scale*1  
  
sample_size = 100
```

Reading

- See notes on Bayesian inference on iML site
(bayes-notes.pdf)
- Not necessary to understand everything—but you should be able to do some of the basic “coin flipping” calculations
- We’ll build on this when discussing topic models

Summary

- Mixtures are latent variable models
- The mixing weight encodes a hidden variable
- Computing with mixtures uses basic probabilistic reasoning
- Bayesian inference is popular in ML
- In a Bayesian approach, the parameters are random, and the data are fixed.
- Three ingredients: Prior, likelihood, posterior

Next up: Topic models

- High level intro to topic models
- Use of latent variables, mixtures
- More details and examples next week

Readings:

<http://www.cs.columbia.edu/~blei/topicmodeling.html>

A survey paper describing many of these ideas in more detail is here:

<https://www.cs.columbia.edu/~blei/papers/Blei2012.pdf>

Topic modeling

Topic modeling provides methods for automatically organizing, understanding, searching, and summarizing large electronic archives.

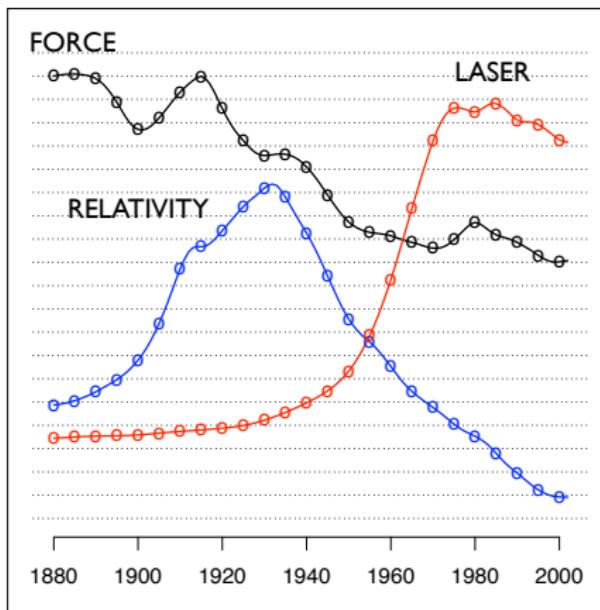

- ① Discover the hidden themes that pervade the collection.
- ② Annotate the documents according to those themes.
- ③ Use annotations to organize, summarize, and search the texts.

Discover topics from a corpus

Uber Topics

From a former student:

Hi Prof. Lafferty,

I took your course last spring. I just wanted to let you know that I'm currently topic modeling at my current job at Uber!

We're using topic models at Uber to discover topics in rider feedback – when riders write comments about their driver after the trip. We're trying to find topics such as 'unprofessional driver', 'driver no-show', 'sexual harassment', etc.

Probabilistic modeling

- ① Data are assumed to be observed from a generative probabilistic process that includes hidden variables.
 - *In text, the hidden variables are the thematic structure.*
- ② Infer the hidden structure using posterior inference
 - *What are the topics that describe this collection?*
- ③ Situate new data into the estimated model.
 - *How does a new document fit into the topic structure?*

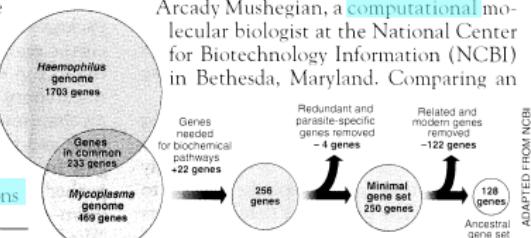

Latent Dirichlet allocation (LDA)

Seeking Life's Bare (Genetic) Necessities

COLD SPRING HARBOR, NEW YORK—How many genes does an organism need to survive? Last week at the genome meeting here,* two genome researchers with radically different approaches presented complementary views of the basic genes needed for life. One research team, using computer analyses to compare known genomes, concluded that today's organisms can be sustained with just 250 genes, and that the earliest life forms required a mere 128 genes. The other researcher mapped genes in a simple parasite and estimated that for this organism, 800 genes are plenty to do the job—but that anything short of 100 wouldn't be enough.

Although the numbers don't match precisely, those predictions

"are not all that far apart," especially in comparison to the 75,000 genes in the human genome, notes Siv Andersson of Uppsala University in Sweden, who arrived at the 800 number. But coming up with a consensus answer may be more than just a genetic numbers game, particularly as more and more genomes are completely mapped and sequenced. "It may be a way of organizing any newly sequenced genome," explains Arcady Mushegian, a computational molecular biologist at the National Center for Biotechnology Information (NCBI) in Bethesda, Maryland. Comparing an

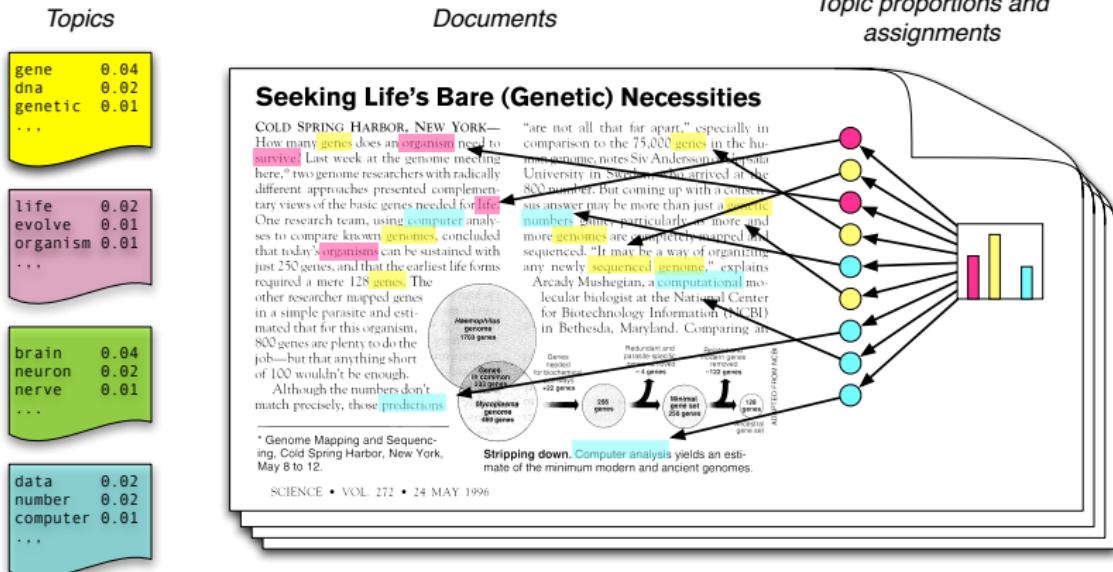

ADAPTED FROM NCBI

Stripping down. Computer analysis yields an estimate of the minimum modern and ancient genomes.

SCIENCE • VOL. 272 • 24 MAY 1996

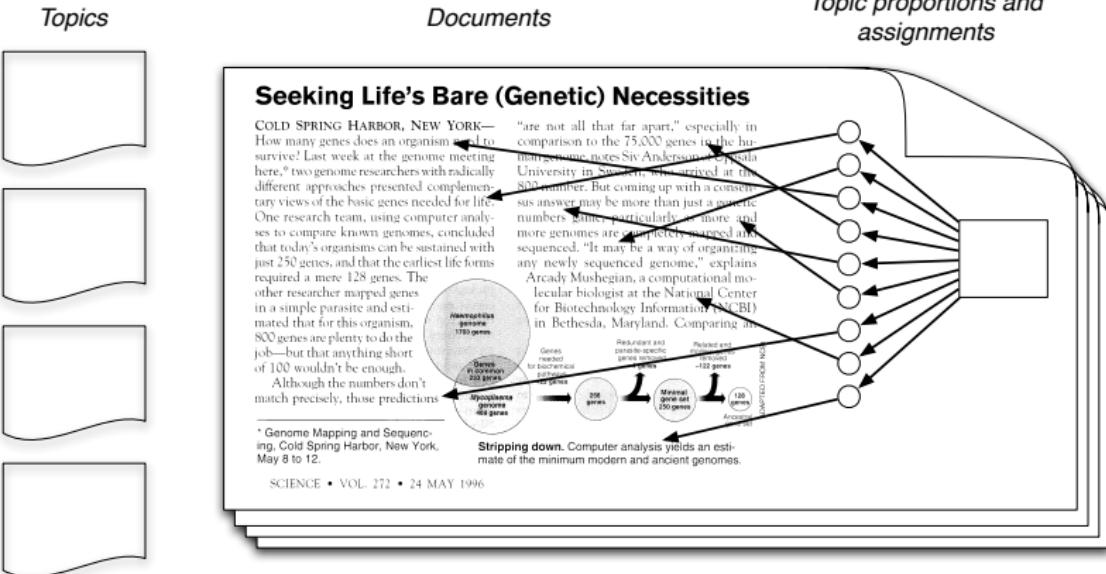

Simple intuition: Documents exhibit multiple topics.

Generative model for LDA

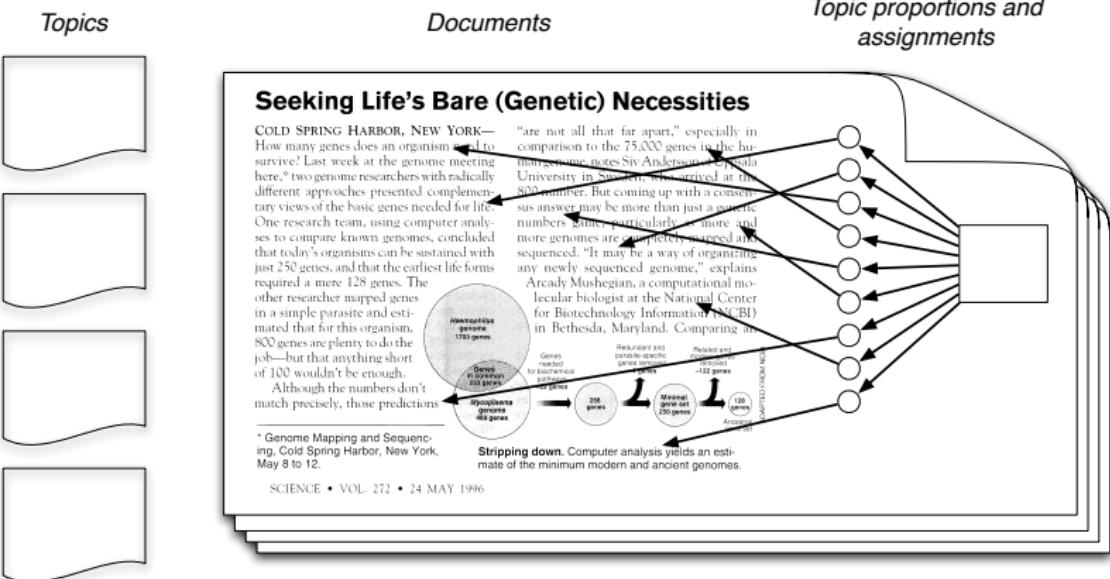

- Each **topic** is a distribution over words
- Each **document** is a mixture of corpus-wide topics
- Each **word** is drawn from one of those topics

The posterior distribution

- In reality, we only observe the documents
- The other structure are **hidden variables**

The posterior distribution

- Our goal is to **infer** the hidden variables
- I.e., compute their distribution conditioned on the documents
 $p(\text{topics, proportions, assignments} \mid \text{documents})$

Summary: Topic models

- Topic models automatically extract “semantic themes” from large document collections
- Based on latent variables, mixtures, and Bayesian inference
- Can be useful for a wide variety of data
