Classification

September 14

Notes

- Assn 1 is posted; due Sept 21 (midnight)
- Please join us at office hours!
- Use Ed Discussion for questions
- Some notes/refs at an appropriate level:
 - ▶ Background concepts: http://www.mit.edu/~6.s085/notes/lecture1.pdf
 - Linear regression: http://www.mit.edu/~6.s085/notes/lecture3.pdf
 - ▶ ISL (Python): https: //hastie.su.domains/ISLP/ISLP_website.pdf

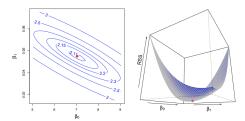

FIGURE 3.2. Contour and three-dimensional plots of the RSS on the Advertising data, using sales as the response and TV as the predictor. The red dots correspond to the least squares estimates β_0 and β_1 , given by (3.4).

The model given by (3.5) defines the population regression line, which is the best linear approximation to the true relationship between X and Y. The least squares regression coefficient estimates (3.4) characterize the least squares line (3.2). The left-hand panel of Figure 3.3 displays these two lines in a simple simulated example. We created 100 random Xs, and generated 100 corresponding Ys from the model

population regression

least squares

$$Y = 2 + 3X + \epsilon, \tag{3.6}$$

3.6.2 Simple Linear Regression

In this section we will construct model matrices (also called design matrices) using the ModelSpec() transform from ISLP.models.

We will use the Boston housing data set, which is contained in the ISLP package. The Boston dataset records medv (median house value) for 506 neighborhoods around Boston. We will build a regression model to predict medv using 13 predictors such as rmvar (average number of rooms per house), age (proportion of owner-occupied units built prior to 1940), and lstat (percent of households with low socioeconomic status). We will use statsmodels for this task, a Python package that implements several commonly used regression methods.

We have included a simple loading function $load_data()$ in the ISLP package:

Outline—Next two classes

- Some important concepts
- Logistic regression
- Generative vs. discriminative
- Gaussian discriminant analysis
- Examples: Supernovae and political blogs
- Regularization
- Algorithms for fitting the models

Working example: Fisher's Iris data

Outline—today

- Some important concepts
- Logistic regression
- Examples in Jupyter: Mushrooms and flowers

 The Coronary Risk-Factor Study (CORIS). Data: 462 males between ages of 15 and 64 from three rural areas in South Africa.

Outcome Y is presence (Y = 1) or absence (Y = 0) of coronary heart disease

9 covariates: systolic blood pressure, cumulative tobacco (kg), ldl (low density lipoprotein cholesterol), adiposity, famhist (family history of heart disease), typea (type-A behavior), obesity, alcohol (current alcohol consumption), and age.

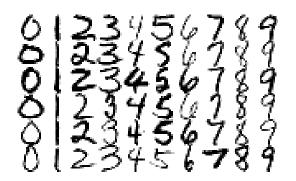

6

 Political Blog Classification. A collection of 403 political blogs were collected during two months before a presidential election. The goal is to predict whether a blog is *liberal* (Y = 0) or conservative (Y = 1) given the content of the blog.

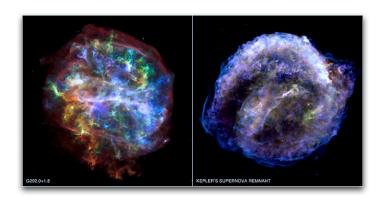

7

Handwriting Digit Recognition. Here each Y is one of the ten digits from 0 to 9. There are 256 covariates X_1, \ldots, X_{256} corresponding to the intensity values of the pixels in a 16 \times 16 image.

 A supernova is an exploding star. Type Ia supernovae are a special class of supernovae that are very useful in astrophysics research. These supernovae have a characteristic *light curve*, which is a plot of the luminosity of the supernova versus time.

ć

 Ad click-through prediction. Predict whether or not a user will click on an ad presented. Used for ranking ads and setting prices.

- The Iris Flower study. The data are 50 samples from each of three species of Iris flowers, Iris setosa, Iris virginica and Iris versicolor. The length and width of the sepal and petal are measured for each specimen based on these features.
- App for wildflowers

Iris setosa (Left), Iris versicolor (Middle), and Iris virginica (Right).

Fisher's iris classification

Iris setosa (Left), Iris versicolor (Middle), and Iris virginica (Right).

Important concepts

Binary classifier h: function from \mathcal{X} to $\{0,1\}$.

Linear if exists a function $H(x) = \beta_0 + \beta^T x$ such that h(x) = 1 if H(x) > 0; 0 otherwise.

H(x) also called a *linear discriminant function*. Decision boundary: set $\left\{x \in \mathbb{R}^d : H(x) = 0\right\}$

Important concepts

Classification risk, or error rate, of h:

$$R(h) = \mathbb{P}(Y \neq h(X))$$

and the *empirical classification error* or *training error* is

$$\widehat{R}(h) = \frac{1}{n} \sum_{i=1}^{n} I(h(x_i) \neq y_i).$$

Optimal classification rule

The optimal rule h^* is called the *Bayes rule*.

The risk $R^* = R(h^*)$ of the Bayes rule is called the *Bayes risk*.

The set $\{x \in \mathcal{X} : m(x) = 1/2\}$ is called the *Bayes decision boundary*.

The Bayes decision rule

Recall Bayes' rule (theorem):

$$\mathbb{P}(A \mid B) = \frac{\mathbb{P}(B \mid A) \, \mathbb{P}(A)}{\mathbb{P}(B)}$$

The Bayes decision rule

From Bayes' theorem

$$\mathbb{P}(Y = 1 \mid X = x) = \frac{\mathbb{P}(X = x \mid Y = 1) \, \mathbb{P}(Y = 1)}{\mathbb{P}(X = x)}$$

$$= \frac{p(x \mid Y = 1) \mathbb{P}(Y = 1)}{p(x \mid Y = 1) \mathbb{P}(Y = 1) + p(x \mid Y = 0) \mathbb{P}(Y = 0)}$$

$$= \frac{\pi_1 p_1(x)}{\pi_1 p_1(x) + (1 - \pi_1) p_0(x)}$$

where $\pi_1 = \mathbb{P}(Y = 1)$.

The Bayes decision rule

The Bayes decision rule is then

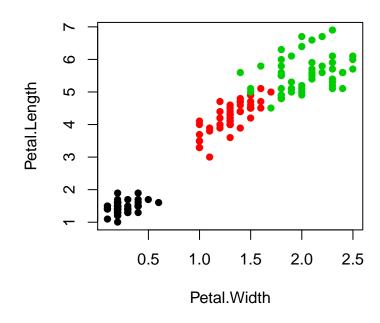

$$\frac{p_1(x)}{p_0(x)} > \frac{1-\pi_1}{\pi_1}.$$

Can be rewritten as

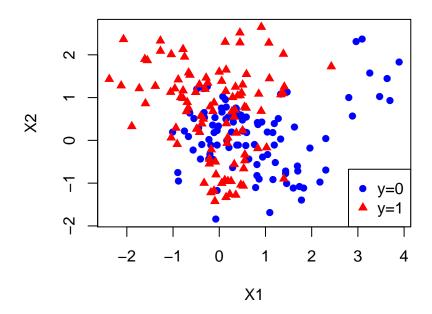

$$h^*(x) = \begin{cases} 1 & \text{if } \frac{p_1(x)}{p_0(x)} > \frac{1-\pi_1}{\pi_1} \\ 0 & \text{otherwise.} \end{cases}$$

Note: These quantities are for the unknown population distribution

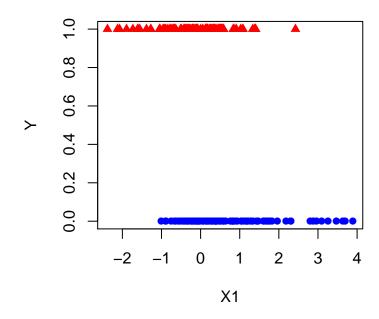

Small dataset example

Simulated data-two classes

Simplification—one predictor

Logistic regression (binary case)

Conditional probabilities of the class:

$$\mathbb{P}(Y_i = 1 \mid X = x_i) = p(x_i)$$

$$\mathbb{P}(Y_i = 0 \mid X = x_i) = 1 - p(x_i)$$

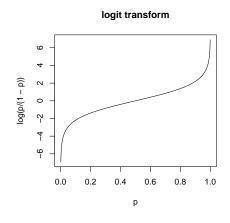

Logistic regression (binary case)

Conditional probabilities of the class:

$$\mathbb{P}(Y_i = 1 \mid X = x_i) = p(x_i)$$

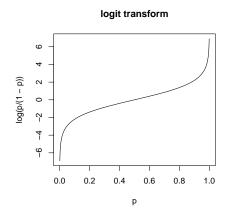

$$\mathbb{P}(Y_i = 0 \mid X = x_i) = 1 - p(x_i)$$

We model the relationship between $p(x_i)$ and x_i .

The *logit* transform:

$$logit(p) = \log\left(\frac{p}{1-p}\right)$$

The *logit* transform:

$$logit(p) = \log\left(\frac{p}{1-p}\right)$$

The logit transform

- is monotone
- maps the interval [0,1] to $(-\infty,\infty)$

Logistic regression is a linear regression model of the log odds:

$$logit(\widehat{p}(x)) = \widehat{\beta}_0 + \widehat{\beta}_1 x$$

- p is a probability.
- $\frac{p}{1-p}$ is odds.
- $logit(p) = log(\frac{p}{1-p})$ is (natural) log odds.

Logistic regression is a linear regression model of the log odds:

$$logit(\widehat{p}(x)) = \widehat{\beta}_0 + \widehat{\beta}_1 x$$

- p is a probability.
- $\frac{p}{1-p}$ is odds.
- $logit(p) = log(\frac{p}{1-p})$ is (natural) log odds.

Equivalent formulation:

$$\widehat{\rho}(x) = \frac{e^{\widehat{\beta}_0 + \widehat{\beta}_1 x}}{1 + e^{\widehat{\beta}_0 + \widehat{\beta}_1 x}} = logistic(x^T \widehat{\beta}) \equiv softmax(x^T \widehat{\beta})$$

• When
$$\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$$
, $\frac{\widehat{p}}{1-\widehat{p}} = 1$, so $\widehat{p} = 0.5$.

- When $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$, $\frac{\widehat{p}}{1-\widehat{p}} = 1$, so $\widehat{p} = 0.5$.
- If our goal is to minimize the overall training error rate, then we use the rule:

$$\widehat{y} = \begin{cases} 1 & \widehat{p} \ge 0.5 \\ 0 & \widehat{p} < 0.5 \end{cases}$$

- When $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$, $\frac{\widehat{p}}{1-\widehat{p}} = 1$, so $\widehat{p} = 0.5$.
- If our goal is to minimize the overall training error rate, then we use the rule:

$$\widehat{y} = \begin{cases} 1 & \widehat{p} \ge 0.5 \\ 0 & \widehat{p} < 0.5 \end{cases}$$

• Hence, the decision boundary is given by $\{x : x^T \hat{\beta} = 0\}$.

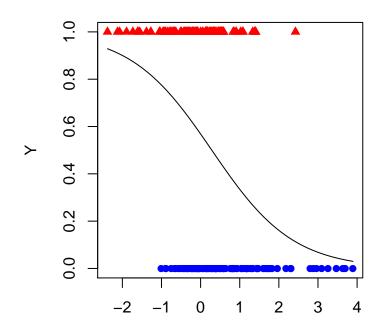

- When $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$, $\frac{\widehat{p}}{1-\widehat{p}} = 1$, so $\widehat{p} = 0.5$.
- If our goal is to minimize the overall training error rate, then we use the rule:

$$\widehat{y} = \begin{cases} 1 & \widehat{p} \ge 0.5 \\ 0 & \widehat{p} < 0.5 \end{cases}$$

• Hence, the decision boundary is given by $\{x : x^T \hat{\beta} = 0\}$.

The decision boundary is linear in x!

Simulated data

Fitting a logistic regression

Traditionally, use maximum likelihood estimation (MLE).

• Likelihood of a single observation (x_i, y_i) :

$$L_i(\beta) = p_i^{y_i} \cdot (1 - p_i)^{1 - y_i} = \left(\frac{e^{x_i^T \beta}}{1 + e^{x_i^T \beta}}\right)^{y_i} \cdot \left(1 - \frac{e^{x_i^T \beta}}{1 + e^{x_i^T \beta}}\right)^{1 - y_i}$$

Fitting a logistic regression

Traditionally, use maximum likelihood estimation (MLE).

• Likelihood of a single observation (x_i, y_i) :

$$L_{i}(\beta) = p_{i}^{y_{i}} \cdot (1 - p_{i})^{1 - y_{i}} = \left(\frac{e^{x_{i}^{T}\beta}}{1 + e^{x_{i}^{T}\beta}}\right)^{y_{i}} \cdot \left(1 - \frac{e^{x_{i}^{T}\beta}}{1 + e^{x_{i}^{T}\beta}}\right)^{1 - y_{i}}$$

Log-likelihood of a single observation:

$$\ell_i(\beta) = y_i \log \left(\frac{e^{x_i^T \beta}}{1 + e^{x_i^T \beta}} \right) + (1 - y_i) \log \left(\frac{1}{1 + e^{x_i^T \beta}} \right)$$
$$= y_i x_i^T \beta - \log(1 + e^{x_i^T \beta})$$

24

Fitting a logistic regression

Traditionally, use maximum likelihood estimation (MLE).

• Likelihood of a single observation (x_i, y_i) :

$$L_{i}(\beta) = p_{i}^{y_{i}} \cdot (1 - p_{i})^{1 - y_{i}} = \left(\frac{e^{x_{i}^{T}\beta}}{1 + e^{x_{i}^{T}\beta}}\right)^{y_{i}} \cdot \left(1 - \frac{e^{x_{i}^{T}\beta}}{1 + e^{x_{i}^{T}\beta}}\right)^{1 - y_{i}}$$

Log-likelihood of a single observation:

$$\ell_i(\beta) = y_i \log \left(\frac{e^{x_i^T \beta}}{1 + e^{x_i^T \beta}} \right) + (1 - y_i) \log \left(\frac{1}{1 + e^{x_i^T \beta}} \right)$$
$$= y_i x_i^T \beta - \log(1 + e^{x_i^T \beta})$$

Sum this over all data points

Extension to more than 2 classes

Multinomial logistic regression extends the logistic regression model to $K \ge 2$ classes.

$$\log \left(\frac{P(Y = k | X = x)}{P(Y = 0 | X = x)} \right) = x^T \beta_k, \quad k = 1, 2, ..., K - 1$$

Extension to more than 2 classes

Multinomial logistic regression extends the logistic regression model to $K \ge 2$ classes.

$$\log \left(\frac{P(Y = k \mid X = x)}{P(Y = 0 \mid X = x)} \right) = x^{T} \beta_{k}, \qquad k = 1, 2, \dots, K - 1$$

$$P(Y = k \mid X = x) = \frac{\exp(x^{T} \beta_{k})}{1 + \sum_{l=1}^{K-1} \exp(x^{T} \beta_{l})}, \qquad k = 1, 2, \dots, K - 1$$

Extension to more than 2 classes

Multinomial logistic regression extends the logistic regression model to $K \ge 2$ classes.

$$\log\left(\frac{P(Y=k \mid X=x)}{P(Y=0 \mid X=x)}\right) = x^T \beta_k, \qquad k = 1, 2, \dots, K-1$$

$$P(Y=k \mid X=x) = \frac{\exp(x^T \beta_k)}{1 + \sum_{l=1}^{K-1} \exp(x^T \beta_l)}, \qquad k = 1, 2, \dots, K-1$$

$$P(Y=\cdot \mid X=x) = \operatorname{softmax}\left(1, \exp(x^T \beta_1), \dots, \exp(x^T \beta_{K-1})\right)$$

Fisher's iris classification

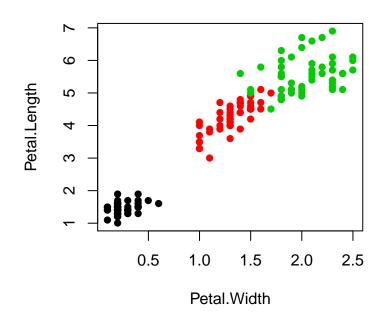

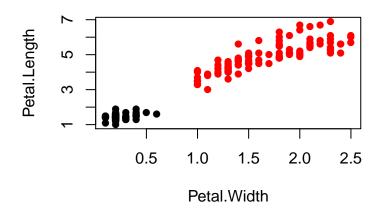

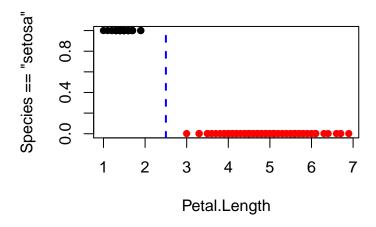

Iris setosa (Left), Iris versicolor (Middle), and Iris virginica (Right).

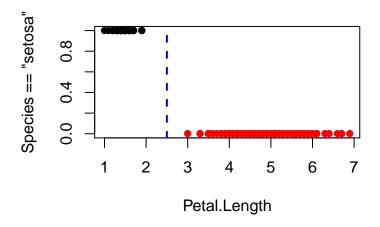

Pretend we only care for predicting setosas (Y = 1) vs. non-setosas (Y = 0):

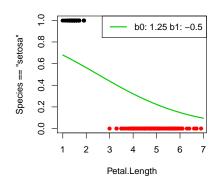

Petal length of 2.5 can perfectly separate Y = 1 and Y = 0 groups.

Decision boundary: $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$.

$$\widehat{\beta}_1 = -\frac{\widehat{\beta}_0}{2.5}$$
 for $\widehat{\beta}_1 < 0$ will yield perfect fits.

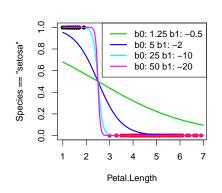

Decision boundary: $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$.

$$\widehat{\beta}_1 = -rac{\widehat{eta}_0}{2.5}$$
 for $\widehat{eta}_1 < 0$ will yield perfect fits.

Decision boundary: $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$.

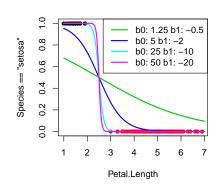

$$\widehat{\beta}_1 = -\frac{\widehat{\beta}_0}{2.5}$$
 for $\widehat{\beta}_1 < 0$ will yield perfect fits.

Int	Slope	Likelihood
1.25	-0.5	0.0000000
5.00	-2.0	0.0001696
25.00	-10.0	0.9846004
50.00	-20.0	0.9999415

Decision boundary: $\widehat{\beta}_0 + \widehat{\beta}_1 x = 0$.

$$\widehat{\beta}_1 = -rac{\widehat{eta}_0}{2.5}$$
 for $\widehat{eta}_1 < 0$ will yield perfect fits.

Int	Slope	Likelihood
1.25	-0.5	0.0000000
5.00	-2.0	0.0001696
25.00	-10.0	0.9846004
50.00	-20.0	0.9999415

As $\|\beta\|$ increases, likelihood approaches 1.

This results in overfitting

Examples in Jupyter notebook

Lets work through some examples in a Jupyter notebook. Please open classification-examples.ipynb and run the notebook as we go through it.

Summary

- In classification we predict a class label
- The default model is logistic regression corresponds to linear regression
- The model is fit to maximize the probability of the data
- If the data are linearly separable, this causes numerical problems
- One parameter for each input variable later we will discuss neural nets and other methods to learn good features of the input
